"The impact of the M1 tank cannot be overstated; while applying lessons learned from mistakes of the past, this new tank defined tanks and armored warfare for the foreseeable future. It redefined how the U.S. Army thought, planned, trained, and fought. The M1 carried the army into an

order-of-magnitude change that ran the gamut of ground warfare. The speed that the army moved across the battlefield was increased, the methods used to supply this faster-moving force were redefined and mastered, the methods used to provide supporting fire from artillery and close-air-support aircraft were redefined and

mastered, and the decision-making process used by the leadership at virtually all levels was accelerated. For the first time in history, the U.S. Army had the best tank in the world. The M1 Abrams became the yardstick for foreign countries potential enemies, and friends alike, to measure the capabilities of their own tanks ... the M1

The crew members of tracked vehicles are affected adversely by low frequency vibrations transmitted to the vehicle compartment from the vibrations

occurring in the track. The noise and vibration level in the crew compartment can cause hearing damage and serious discomfort to the crew members resulting in serious degradation of efficiency. These noise and vibration are caused by the transmission of the vibrations occurring in the track as it leaves the rear road wheel

and goes over the idler and engages the sprocket. The chordal action in various parts of the track corresponding to the resonance-type vibrations also contribute to the noise and vibration. These factors, therefore, indicate loss of energy generated by the engine in addition to the discomfort to the crew. This is an analytical study of

the vibrations generated by the track of tracked vehicles. A method of analysis is derived from the technique of receptance calculation. By this means, the ratio of displacement at the idler wheel support to a periodic force applied at the rear road wheel, as the track pads strike the road, is calculated. This ratio can be obtained with

due regards to the various physical parameters describing the characteristics of the track configuration and the boundary conditions at the idler wheel support. Analysis of forces acting on the idler wheel support also yields results describing favorable idler wheel configuration, compliance of idler arm,

and the size of the track shoe assembly. Combination of these results can be used to predict optimum conditions under which the vibration of a prescribed frequency can be minimized. Actual vehicles operating under various terrain conditions will be used.
